28/01/2026

*Thanks to Veneto Lavoro, Piedmont Region, and CERVED for the data and to Ling Zhong, Francis Kramarz, Claudio Labanca and to the participants of the Milan PhD Workshop, VET4GROWTH and AIEL conferences for the discussions.

Introduction

- Small firms are the majority worldwide: in OECD countries 80% have < 10 employees (OECD, 2021)
- Small firm growth, targeting financial and regulatory constraints, managerial skills (Manaresi et al., 2022) and skill gaps, is essential for employment, wage and productivity \uparrow (Card et al., 2018; Card, 2022)
- Key Dimensions:
 - ① **Age** Young firms hire young workers, pay higher wages, and grow more (Ouimet and Zarutskie, 2014)
 - ② Capital/labor substitution or complementarity
 - ③ Productivity, profitability, and efficiency
 - ④ Hiring profiles (contract type, security, schedule, qualification, age, edu level)
- Size $\uparrow \rightarrow$ TFP and K/L \uparrow (Bjuggren, 2018, JPE)
 - * Productivity \uparrow only for older firms \rightarrow Mixed evidence on firm age

This Paper

We investigate the impact of small firm scaling on firms' capital-labor choice, productivity, and efficiency

Exploit the Fornero Reform to find an exogenous threshold that incentives firm growth

Combine firm-level and matched employer-employee data and use a *Diff-in-IV* strategy

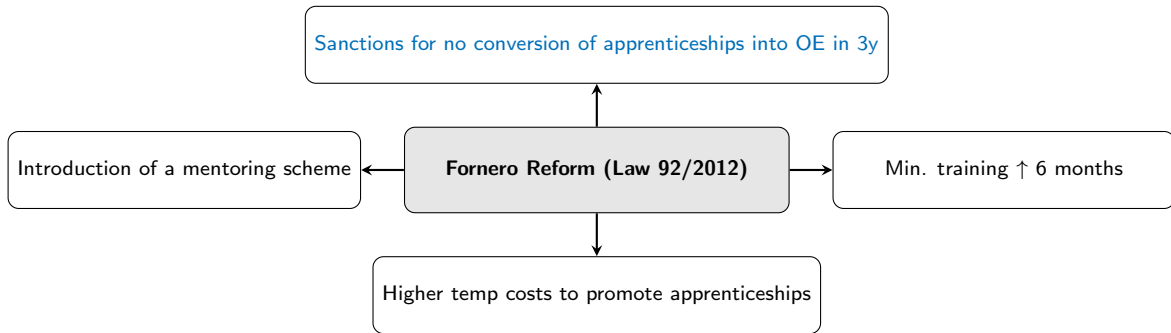

Investigate heterogeneity over time and across sectors

Preview

- Firm size growth leads to \uparrow production outcomes but less proportionally
- ROE, ROA, ROI, and ROS are unaffected, suggesting that growth does not \uparrow efficiency
- Size \uparrow driven by complementary standard workers and apprentices
- *Synchronous Production Theory* firms evolve toward FT schedules
- Dynamics \uparrow for standard apprentices, \downarrow sales, revenues, and VA, while not on TFP
- Higher effects for younger and manufacturing/construction firms

The *Fornero* Reform

- Apprentice contract (*apprendistato professionalizzante* or AP) was introduced in '03 for 15-29y only
- VET (Vocational Education and Training or *apprendistato 1st livello*) contract is a training agreement where students combine classroom education with on-the-job internships
- Firms failing to match the *Fornero* Requirements are forbidden to hire ANY apprentice in the future

Fornero Reform (Law 92/2012)

- Introduced size-dependent regulation of apprenticeship contracts
- A sharp institutional threshold arises at $L = 10$ employees:
 - ▶ Firms with $L < 10$ face no binding apprenticeship quotas and no conversion-rate sanctions
 - ▶ Firms with $L \geq 10$ are subject to quantitative limits and penalties for low conversion rates
- The cutoff is exogenously determined: absent the reform, firms below/above would evolve smoothly

The Reform incentivised firms to grow

Firms above the cutoff must have apprentices in quotas over the workforce, pushing to complement apprentices with other workers, while simultaneously apprentices become relatively less costly

- We exploit #firms transiting pre/post reform to identify the causal effect: *Reform* \Rightarrow *Size* \Rightarrow *Firm outcomes*

Data and Sample Selection

- **Comunicazione Obbligatorie (CO)** Universe of Piedmont and Veneto plant flows in '09-19
 - * We focus on qualification, occupation, edu level, age, contract type
- **CERVED** firms' balance records and size (INPS) at the yearly level in 2009-19
 - * We focus on size, VA, capital, efficiency and profitability measures, TFP
- We select *growers* *i.e.*, firms whose baseline size (in '09) is between 5 and 9 employees and monotonically increases in '10-14 (JA in '15) up to 30 employees
 - * *e.g.*, firm with 5 employees in '09, increases to 6 in '12 and doesn't decrease up to '14
 - * Why *growers* only? because non-growers are bad controls
- Unbalanced panel of $\sim 9k$ plant-year tuples and 2k plants in 2010-14

▶ Veneto & Piedmont

▶ Stats

▶ Age histograms

▶ Balancing

Firm Age and Firm Size

- *Growers* firms are younger: younger firms are smaller at the baseline but grow more over time

Firm baseline size vs firm birth year.

Firm size vs firm birth year over time

#transitions and #apprentices before and after the reform

#transitions pre and post.

#apprentices (AP + VET) pre and post.

Notes: The first panel plots #firms crossing the 10-employee threshold pre (2010–11) and post (2012–14) reform. The second panel plots #apprentices contracts (AP + VET) across the same bins pre and post reform.

Econometric Intuition

- We follow *Alsan et al. (2025, QJE) Difference-in-IV (DIV)*
- Consider a firm scaling up before or after the policy and decompose its outcomes as;

$$Y_j = Y_j(0) + \theta^B SB_j + \theta^A SB_j \times Post_j \quad (1)$$

- $Y_j(0)$: untreated potential outcome *i.e.*, the outcome that firm j would experience without scaling
- $Post_j=1$ if firm j scales up after the reform; SA_j : firm size after = $SB_j \times Post_j$
- Two endogenous variables; one before and one after policy
- θ^B : Baseline effect of size on firm j ; θ^A : Incremental effect of size growth due to the reform
- **Assumptions** 1 Firms didn't anticipate the reform; 2 Z s are positively correlated with the endogeneous variables; 3 Z s affect firm j outcome only through changes in size

Empirical Strategy

- We estimate:

$$\ln Y_{jt} = \alpha_j + \beta_t + \gamma_{st} + \theta^B \hat{Size}_{jt}^B + \theta^A \hat{Size}_{jt}^A \times Post_t + \epsilon_{jt} \quad (2)$$

- ✱ 1st stage:

$$Size_{jt} = \alpha_j + \beta_t + \gamma_{st} + \delta_{o,s} Z_{o,d}^B + \Theta_{o,s} Z_{o,d}^A + \epsilon_{jt} \quad (3)$$

- Y_{jt} is an outcome of firm j in year t . α , β , and γ are firm, year, and 2d industry by year FE
- θ^A is the difference between two LATEs ($\theta^A - \theta^B$) identifying the incremental effect on Y
- Z is a dummy=1 is firm crossing the 10-employee threshold, pre and post policy
- Firm-level clustered standard errors

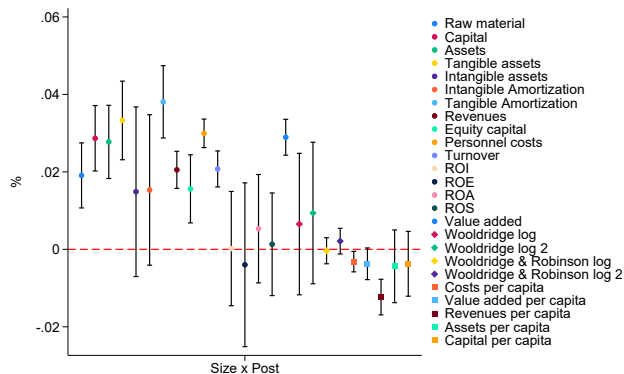

Baseline Effects

1st Stage: Size

Notes: Reduced-form difference of $\delta_{o,s}$ and $\Theta_{o,s}$ from Eq. (3). Size in level. 95% CI. Firm-clustered SE.

◀ 1st stage statistics

2nd Stage: Other outcomes

Notes: Estimates of θ^{Δ} from Eq. (2). Outcomes in logs; coefficients are semi-elasticities. 95% CI. Firm-clustered SE.

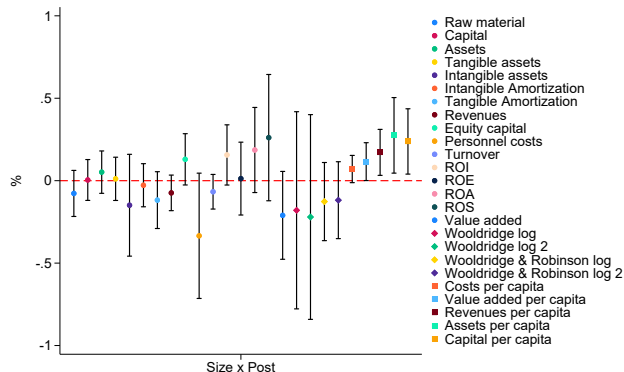

Placebo

- We select firms below the 10-employee threshold exploiting 0-4 → 5-9 transitions ($Z_{1,2}$)

1st Stage: Size

Notes: Reduced-form difference of $\delta_{1,2}$ and $\Theta_{1,2}$. Size in level. 95% CI. Firm-clustered SE.

2nd Stage: Other outcomes

Notes: Estimates of placebos θ^{Δ} . Outcomes in logs; coefficients are semi-elasticities. 95% CI. Firm-clustered SE.

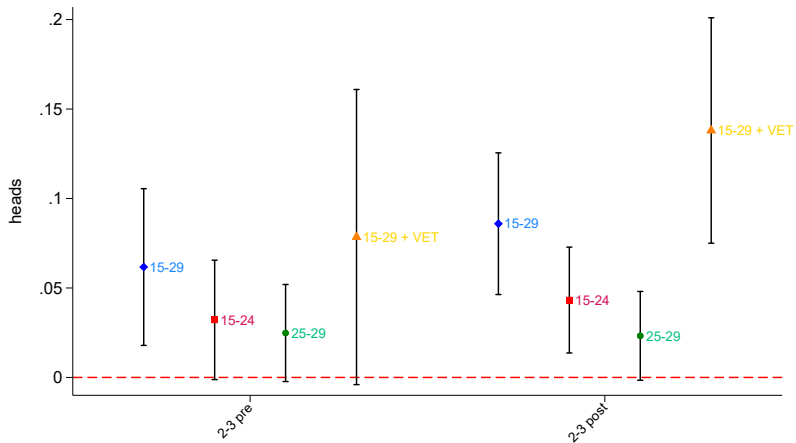

Mechanisms: *Synchronous Production Theory*

- **Labanca & Pozzoli (JOLE, 2022; JHR, 2023)** Supervision, mentoring, on-the-job learning require co-presence → Firms move toward cooperative, team-based technologies → ↓ dispersion of working hours + ↑ full-time + ↓ part-time **!Productivity is not additive but arises from interaction!**
- We estimate this reduced-form OLS specification:

$$Hirings_{jt} = \alpha_j + \beta_t + \gamma_{st} + \delta_{o,s}Z_{o,d}^B + \Theta_{o,s}Z_{o,d}^A + \epsilon_{jt} \quad (4)$$

- Hirings separated by contract type, occupation, time schedule, age, and edu level
- $Z_{o,s}^{B,A}$ is a dummy=1 if firm j crosses the 10-employee threshold before and after the reform
- α , β , and γ are firm, year, and industry-year FE
- Firm clustered SE

Apprentices

Notes: Graph plots the reduced-form estimates $\delta_{O,S}$ and $\Theta_{O,S}$ of Eq. (4). Outcomes in levels. 95% CI. Firm clustered SE. Only significant outcomes are displayed.

Hirings by Contract Type and Age

By Contract Type.

By Age.

Notes: Graph plots the reduced-form estimates $\delta_{o,s}$ and $\Theta_{o,s}$ of Eq. (4). Outcomes in levels. 95% CI. Firm clustered SE.

Hirings by Educational Level and Occupation

By Educational Level.

By Occupation.

Notes: Graph plots the reduced-form estimates $\delta_{o,s}$ and $\Theta_{o,s}$ of Eq. (4). Outcomes in levels. 95% CI. Firm clustered SE.

More

- **By Sectors** stronger effects in manufacture/construction (TFP \uparrow and PC Ys \approx) particularly 4321/4322
- **Dynamics Estimates** all estimates decrease over time: in '19 they become null

Summing Up

- Scaling up \uparrow all outcomes \rightarrow Firms produce at a higher isoquant
- Null effects on ROS, ROI, ROE, ROA and unclear on TFP \rightarrow Unclear efficiency improvements
- 1 \uparrow in apprentices driven by VET; 2 \uparrow older low-qualified workers and \downarrow youngest workers \rightarrow Effects driven by complementarity between apprentices and FT older workers
- \uparrow standard apprentices + attenuated effects over time
- Stronger effects for younger firms in manufacturing/construction
- Results support synchronous production theory (Labanca & Pozzoli, 2022;2023)

Next

- Extend to all of Italy (VisitINPS?)

Thanks

Piedmont and Veneto

[◀ back](#)

- Veneto's GDP is 180.5b; $\sim 9.3\%$ of Italy's GDP. Piedmont's GDP is 146.2b; $\sim 7.5\%$ of Italy's GDP
- Veneto has $\sim 500,000$ businesses, mainly in manufacturing and services; Piedmont 400,000
- Veneto accounts for $\sim 10\%$ of Italy's workforce, Piedmont 8%
- In 2012 there were 1206 municipalities in Piedmont and 581 in Veneto
- We cover $\sim 18\%$ of Italy's GDP and workforce; 900k firms; 1787 municipalities

Firm Size

Effects driven within Construction [◀ back](#)

- Specialised Construction Activities (43) → [Electrical, Plumbing, and heat installation \(4321, 4322\)](#)

- Firms may need time to change strategies and address inefficiencies
- We estimate a **dynamic specification adding cumulatively one year at a time up to '19**:

$$\ln Y_{j,t+i} = \alpha_j + \beta_{t+i} + \gamma_{s,t+i} + \theta^B \hat{Size}_{j,t}^B + \theta^A \hat{Size}_{j,t}^A \times Post_{t+i} + \epsilon_{j,t+i} \quad (5)$$

, with $i = [1 : 5]$, $t = [2010 : 2014]$, and $t + i$ going from 2015 to 2019

- Zs are exactly those of the baseline: no transition allowed post '14 → The sample of firms and their size is the same as the baseline; we only extend the window of analysis
